

DFCs Overview

For more information on entities backward compatibility, refer to **Database Architecture Transition Guide**.

Main Entities

Icon	Entity Description
	DFC: a data flow control (DFC) is a core entity that help create logic for various applications by managing the flow of data using, for example, functions.

Entity Components

Icon	Component Description
	Step: the child component of a DFC. It is a container for functions and allows for building routing between different DFC steps. The steps are not reusable, but they might be copied.
	Function: the child component of a DFC step with the capability to create and use business logic. It consists of inputs and outputs (linked to business logic) that perform specific business functions. They may be used to perform data collection, data transformation, control DFC step navigation, invoke business logic, and more.
	Input: the child component of a function. It incorporates the data received by a function to be used when processing the function's logic.
	Output: the child component of a function. It incorporates the data sent by a function to be used further down the data flow.
