

Errors and Messages

Managing Screens in Process Builder includes an improved way of raising errors and displaying messages.

Displaying Error Messages

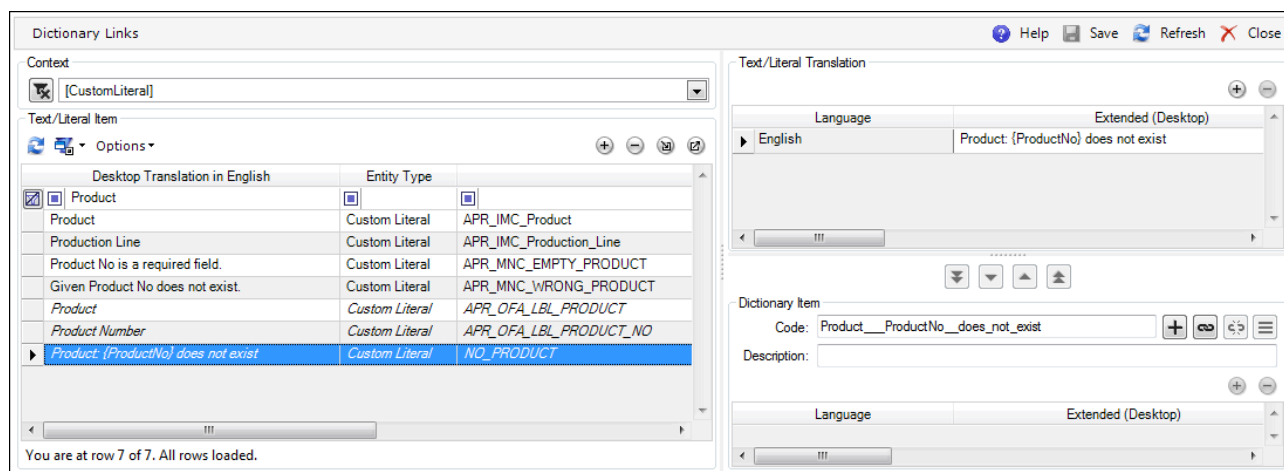

To display the error message:

1. Navigate to **Dictionary** screen and open **Dictionary Links**.
2. Change the **Context** filter to **[CustomLiteral]**.
3. Add a new Literal: **NO_PRODUCT**.

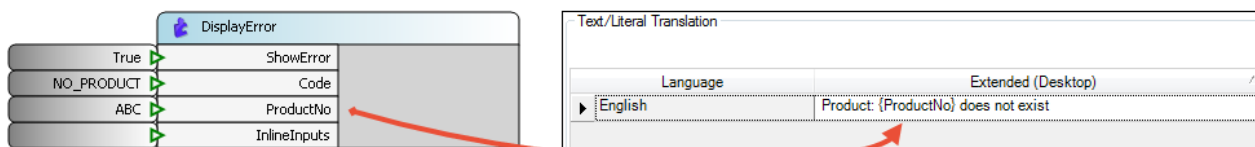

4. After creating the literal, add its translation, for example:

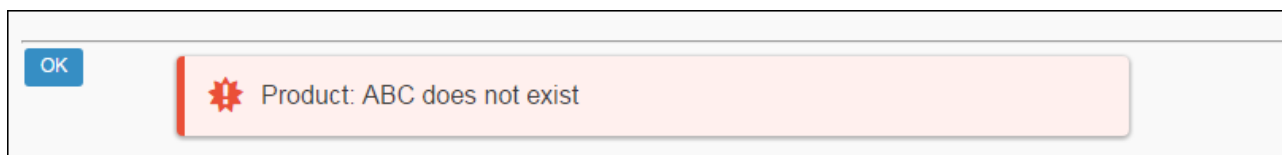

Product: {ProductNo} does not exist

5. Use the **DisplayError** Business Component:

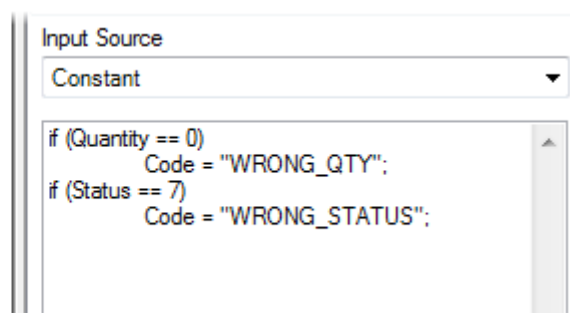

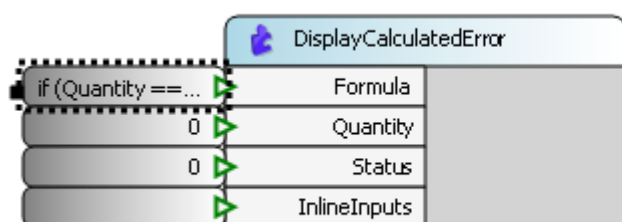

6. The message displayed will be as follows:

The Business Component (BC) behavior is exactly the same as that of the standard **Show Message Function**, except that the Code Input should contain the message code defined in the custom literal. The BC does not support displaying an error in a pop-up window.

To get a formatted message without raising an error, use the **GetPortalMessage** BC.

If you need to calculate if the error should be displayed (in a **User Formula Function**), consider using the **DisplayCalculatedError** BC, which takes the formula to be executed as the Input:

Inside the formula, assign the message code (from the custom literal) to **Code** if you want to display an error. If a **Code** is empty, the error will not be displayed.

Messages

A message can be used to inform or warn the user about a specific situation:

- ▶ The message code should first contain the main entity to which it is referring as well as information about the message type or validation type that can trigger its display
- ▶ The message must be written in all caps (e.g., **PRODUCT_LOCATION_ERROR**, **CONTAINER_LOCATION_INVALID**)
- ▶ The message content can also contain variables (e.g., "Product: {ProductNo} does not exist")
