

Processes (Deprecated) and Operations Overview

For more information on entities backward compatibility, refer to **Database Architecture Transition Guide**.

Main Entities

Icon	Entity Description
	Process: the top-level entity in the process model. It is a collection of process operations, operations, resources, and materials with links to specifications and sample plans. In addition, processes contain roles, skills, work instructions, and other details specifying everything that is necessary to perform the activity properly. The functionalities related to process authoring are deprecated and will not be further developed.
	Process operation: the child entity of a process. It is the unit of manufacturing that is to be performed at a work center by resources that consume materials. It usually models one activity performed by one person in one place at one time. It is a collection of steps, resources, and materials with links to specifications. Process operations are not reusable.
	Operation: a stand-alone entity with the same structure as a process operation. Operations might be consumed by processes or used more independently in a specific order explosion procedure. It is a collection of steps, required resources, and materials with links to specifications. Operations are reusable.

Entity Components

Icon	Component Description
	Step: the child component of a process operation or operation. It is a collection of resources and materials with links to specifications and sample plans. Steps are not reusable, but they might be copied.
	Links and task permissions: links are available for processes, process operations, operations, and operation steps. Tasks permissions can be added to process operations, operations, or their steps.

Processes and Operations in Projects

Starting with DELMIA Apriso 2025, in PB projects, you can add processes and operations only to GPM modules. When upgrading from previous versions, processes and operations from PB modules are converted and moved to the automatically created GPM module called *ImportedProcessesAndOperations*. To ensure proper deployment, this module contains automatically added references to the source PB modules. To make the relocated operations unique and easier to identify, they follow the naming convention: *OperationCode_ProjectCode*.

In **PB projects**, processes and operations exist in GPM modules only as links. You can add the entities using the **Add Existing** option, but most functionalities – for example, **status change** or **duplication** – are limited in GPM modules and available only in Entity Manager. Removing processes or operations from projects only unlinks them and does not remove them from the system. Unlinked entities remain in Entity Manager. Having only non-default revisions of processes and operations in a GPM module is possible.
