

Scan

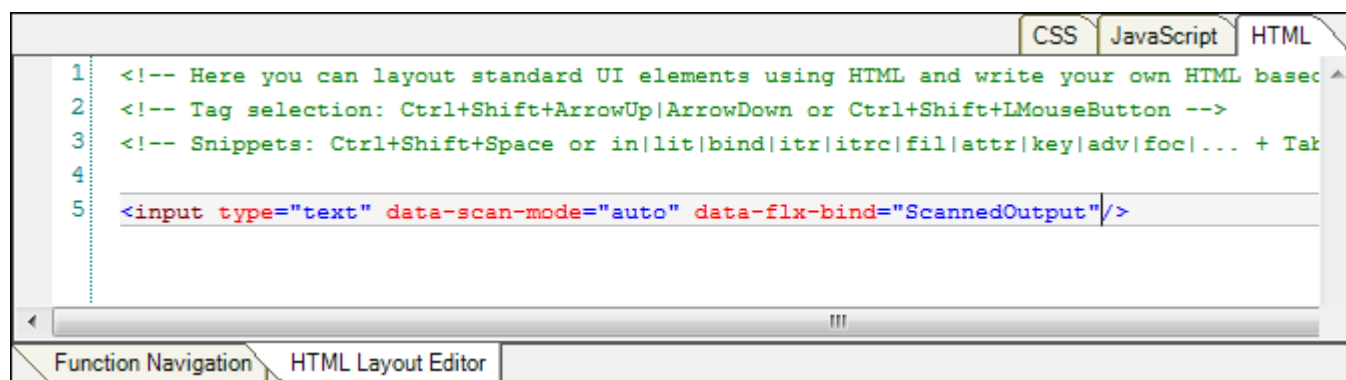

Data-scan attributes are used to configure code scanning in mobile applications. The attributes can be appended to text-type input tags.

For more information about the attributes described in this topic, as well as possible values, see the **Data-scan Attributes** section in the *DELMIA Apriso Mobile Apps Guide*.

Data-scan-mode

Data-scan-mode is the only required attribute.

Scanning can happen in two modes: button or auto. If the **button** mode is selected, the user needs to press a button to begin scanning. In the **auto** mode, scanning is initiated when the user highlights the appropriate text field.

Data-scan-type

Sets the code type. For a list of supported code types, see the *DELMIA Apriso Mobile Apps Guide*.

Data-scan-length

Sets the code length, which must be an exact value.

Data-scan-format

Describes the expected shape of the code.

Data-scan-sign-substitution

Specifies which characters of the code should be replaced by other characters. This is especially useful when a barcode contains special characters (for example, non-printable ones).

Data-scan-postfix

Adds characters to the end of the code displayed in the text field.

Data-scan-area-size

Reduces the size of the scanning area. This is useful when multiple codes are visible in the camera and you want to scan only one specific code.
