

Screen Interface Function Usage

A `$Context` object – a representation of a [screen interface function](#) – is available in the HTML layout editor. For more information on the `$Context` methods, refer to [HTML Layout Editor API Documentation](#).

You can use the `$Context` object only in the HTML tab.

- ▶ `$Context.inputs` - allows you to access inputs.
- ▶ `$Context.outputs` - allows you to access outputs.
- ▶ `$Context.literals` - allows you to access literals.
- ▶ `$Context.view` - allows you to access current view.
- ▶ `$Context.showWorkInstructions()` - allows you to display work instructions.
- ▶ `$Context.submit()` - submits the view. You can use this method in client mode to update external outputs – this action refreshes the screen in the server mode.
- ▶ `$Context.callDFC()` - allows you to call a DFC asynchronously. For more information, see [Using AJAX](#).

Usage Examples
