

Use Action Scripts in Projects

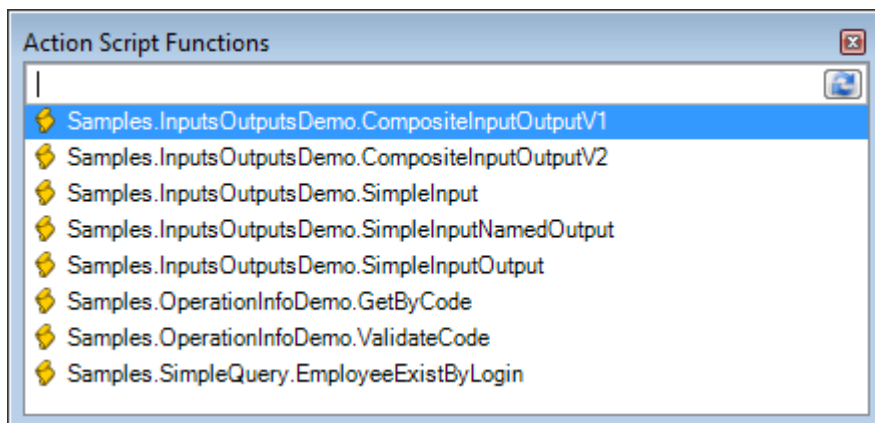

In the sample scenario presented below, you will link existing Action Scripts to entities in your Project. You will also learn how to create new Action Scripts to be used only inside the Project.

To learn more about Action Scripts, see [Action Scripts Overview](#) and subsequent topics.

1. Create a Project with two Modules containing a **Screen** with a linked **Layout** (for instructions, see [Create a Project](#)).
2. Open the Screen and go to the Properties tab.
3. In the **On Initialize** field, select Action Script Function and click  (Link) (for more information about available options, see [Screen: General Tab](#)).

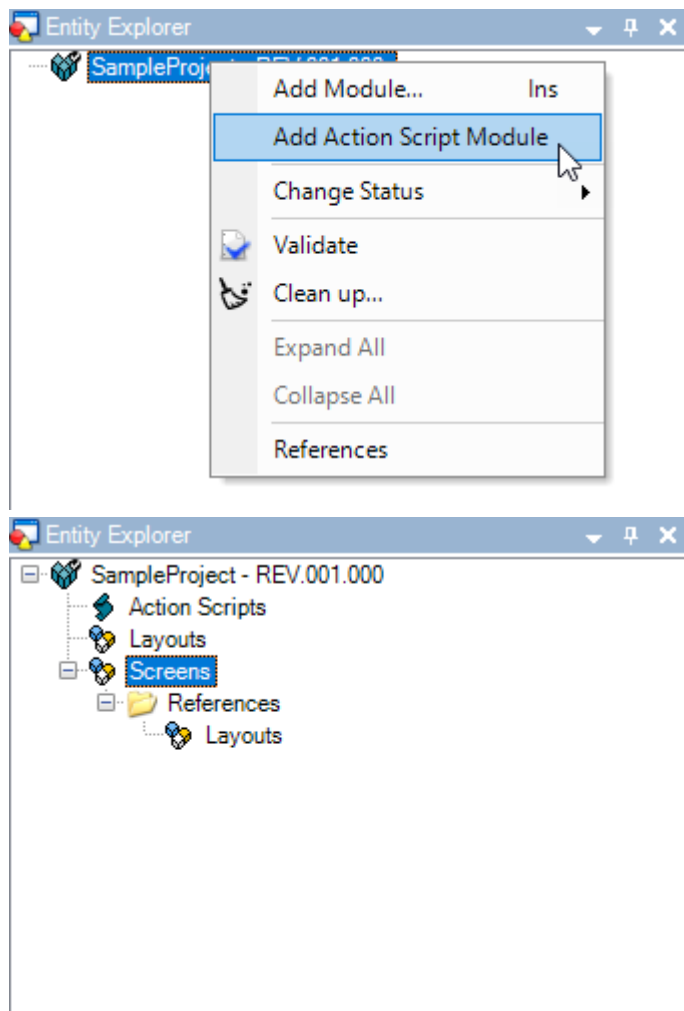

4. You will see a list of all Action Script functions available for linking in your Screen. Choose any of them. You have successfully linked an external Action Script function to your Screen.

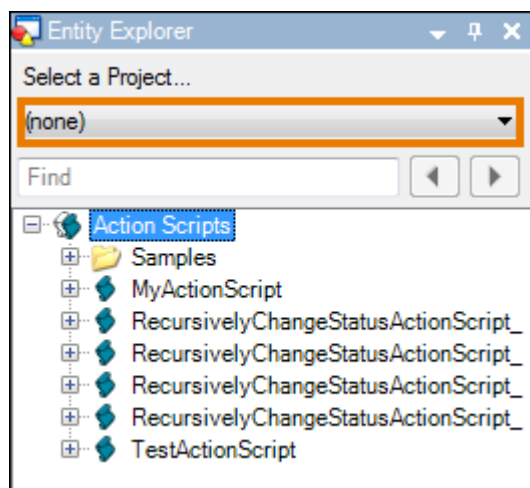

5. To be able to create Action Scripts for use only in your Project, you need to add an **Action Script Module**: right-click your Project node and select Add Action Script Module. A special Module will be added to the Project tree.

The Action Script Module is unlike other Modules in that it is not a container for entities, but rather indicates the ability to use Project-specific Action Scripts. However, it can be deleted and referenced just like any other Module (see [Action Scripts](#) for more information).

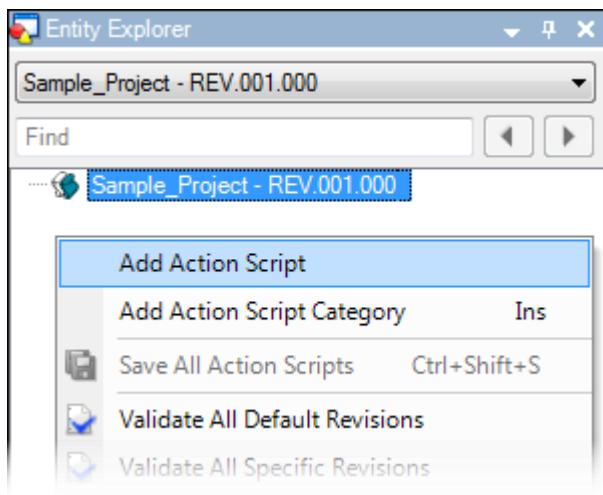

6. You will now create an Action Script for use just in your Project: choose  (Action Script Manager) from the **Managers** Menu or from the **Toolbar**.
7. In the Action Script Manager's Entity Explorer pane, find your Project in the **Select a Project...** drop-down list.

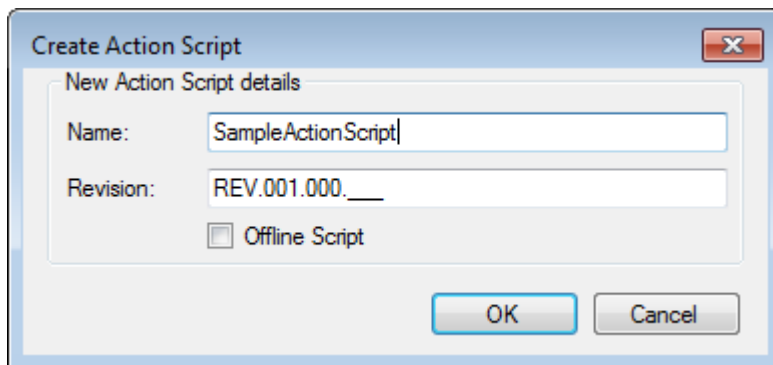

8. Right-click anywhere in the Entity Explorer and select **Add Action Script**.

Action Scripts added to a specific Project will only be available in that Project.

9. Choose a name for your Action Script and click **OK**.

If you want to use the new Action Script in an [Offline Module](#), check the **Offline Script** box. This adds the `ActionScript.OfflineScript` extension to your base class.

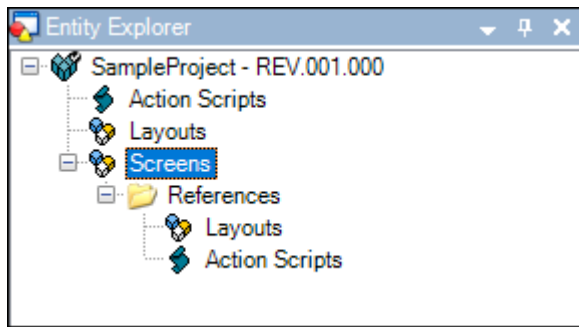

10. As only Action Scripts with a status or **Prototype or higher** can be linked by Project entities, right-click the newly-created Action Script revision and select **Change Status ► Prototype**.

Remember that the namespace of your Action Script must be the same as the name of the Project you want to use it in.

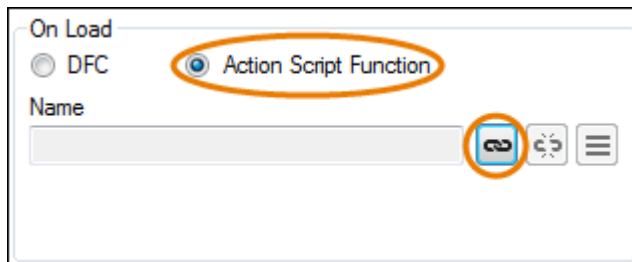

11. Compile the Action Script by selecting  (Compile) from the toolbar.
 12. Before you can use the Action Script created above in your Screen, you must first reference the Action Scripts Module in your Screens Module:

To learn more about References, see [Modules: References](#).

- Right-click the Screens Module and select **References...**
- In the References window that appears, mark the check box next to **Action Scripts** and click **OK**.
- Your Project tree should now look like this:

13. Open your sample Screen and go to the **Properties** tab. In the **On Load** field, select Action Script Function and click  (Link).

14. You will see that the list of Action Script functions available for linking in your Screen now includes the ones from the Action Script added in step 9. Select any of them. You have successfully linked a Project-specific Action Script function to your Screen.
